Hello World, part 2

Agenda for today

Today we're going to go quickly back over loading data and then return to the topic of filtering, selecting and arranging data. We'll then turn to some calculations using the concepts of summarizing (self explanatory) and mutating (creating new variables).

Load relevant libraries

```
## Get necessary libraries-- won't work the first time, because you need to install them!
library(tidyverse)
```

```
## -- Attaching packages -----
                                 ----- tidyverse 1.3.1 --
## v ggplot2 3.3.5
                   v purrr
                           0.3.4
## v tibble 3.1.6
                   v dplyr
                           1.0.7
## v tidyr
         1.1.4
                   v stringr 1.4.0
## v readr
          2.1.1
                   v forcats 0.5.1
## -- Conflicts ----- tidyverse conflicts() --
## x dplyr::filter() masks stats::filter()
## x dplyr::lag()
                 masks stats::lag()
```

Load The Data

```
df<-readRDS("sc_debt.Rds")
names(df)</pre>
```

```
[1] "unitid"
                          "instnm"
                                            "stabbr"

```

Name	Definition
unitid	Unit ID
instnm	Institution Name
stabbr	State Abbreviation
grad debt mdn	Median Debt of Graduates
control	Control Public or Private
region	Census Region
preddeg	Predominant Degree Offered: Associates or Bachelors
openadmp	Open Admissions Policy: 1= Yes, 2=No,3=No 1st time students
adm_rate	Admissions Rate: proportion of applications accepted
ccbasic	Type of institution—see here
selective	Institution admits fewer than 10 % of applicants, 1=Yes, 0=No
research u	Institution is a research university 1=Yes, 0=No
sat avg	Average Sat Scores
md earn wne p6	Average Earnings of Recent Graduates

Name	Definition
ugds	Number of undergraduates

Looking at datasets

We can use "glimpse" to see what's in a dataset. This gives a very quick rundown of the variables and the first few observations.

glimpse(df)

```

```

Types of Variables

Notice that for each variable, it shows a different type, in angle brackets <>. So for instance, instnm has a type of <chr>>. This is short for character—it's also called a string variable.

Here are the types of data in this dataset

- <int> Integer data
- <chr>> Character or string data
- <dbl> Double, (double-precision floating point) or just numeric data— can be measured down to an arbitrary number of data points.

This information is useful, because we wouldn't want to try to run some kind of numeric analysis on string data. The average of institution names wouldn't make a lot of sense (but it would probably be Southeast North State University College).

We'll talk more about data types later, but we should also quickly note that there are some variables in this dataset where the numbers represent a characteristic, rather and a measurement. For instance, the variable research_u is set up—coded— such that a "1" indicates that the college is a research university and a "0" indicates that it is not a research university. The 1 and 0 don't measure anything, they just indicate a characteristic.

Filter, Select, Arrange

Today, we'll pick up where we left off- with the key commands of filter, select, and arrange.

In exploring data, many times we want to look at smaller parts of the dataset. There are three commands we'll use today that help with this.

- -filter selects only those cases or rows that meet some logical criteria.
- -select selects only those variables or columns that meet some criteria
- -arrange arranges the rows of a dataset in the way we want.

For more on these, please see this vignette.

We can look at the first 5 rows:

## #
      research_u <dbl>
```

Using filter in combination with other commands

filter can be used with any command that retruns true or false. This can be really powerful, for instance the command str_detect "detects" the relevant string in the data, so we can look for any college with the word "Colorado" in its name.

```
df%>%
  filter(str_detect(instnm, "Colorado"))%>%
  select(instnm, adm_rate, sat_avg)
```

##	2	University of Colorado Colorado Springs	0.872	1136
##	3	University of Colorado Boulder	0.784	1276
##	4	Colorado Christian University	NA	NA
##	5	Colorado College	0.135	NA
##	6	Colorado School of Mines	0.531	1342
##	7	Colorado State University-Fort Collins	0.814	1204
##	8	Colorado Mesa University	0.782	1063
##	9	University of Northern Colorado	0.908	1096
##	10	Colorado State University Pueblo	0.930	1047
##	11	Western Colorado University	0.842	1114
##	12	Colorado State University-Global Campus	0.986	1048

We can combine this with the | operator, which remember stands for "or." Let's say we want all the institutions in Colorado OR California.

```
df%>%
  filter(str_detect(instnm, "Colorado") | str_detect(instnm, "California"))%>%
  select(instnm,adm_rate,sat_avg)
```

```
## # A tibble: 57 x 3

                                                                            985
## 10 California State Polytechnic University-Pomona
                                                                0.546
                                                                           1143
## # ... with 47 more rows
```

Reminder: logical operators

Here are (many of) the logical operators that we use in R:

- >, <: greater than, less than
- >=, <=: greater than or equal to, less than or equal to
- ! :not, as in != not equal to
- & AND
- | OR

Extending Select

Select can also be used with other characteristics.

For quick guide on this: https://dplyr.tidyverse.org/reference/select.html

For example, we can select just variables that contain the word "region"

```
df%>%
  select(contains("region"))
```

```
## # A tibble: 2,546 x 1
##
      region
##
      <chr>
    1 Southeast
##
##
    2 Southeast
##
    3 Southeast
##
   4 Southeast
##
   5 Southeast
##
    6 Southeast
##
    7 Southeast
##
   8 Southeast
##
   9 Southeast
## 10 Southeast
## # ... with 2,536 more rows
```

We can also select just variables that

```
df%>%
  select(where(is.numeric))
```

```
## # A tibble: 2,546 x 11
##
      unitid grad_debt_mdn openadmp adm_rate ccbasic sat_avg md_earn_wne_p6 ugds
##
       <int>
                      <int>
                                <int>
                                          <dbl>
                                                   <int>
                                                           <int>
                                                                            <int> <int>

## # ... with 2,536 more rows, and 3 more variables: costt4_a <int>,
       selective <dbl>, research_u <dbl>
```

^{*}Quick Exercise: Select colleges that are from Texas AND have the word "community" in their name (the name variable is instnm).

Quick Exercise Use the same setup to select only character variables (is.character)

Summarizing Data

To summarize data, we use the **summarize** command. Inside that command, we tell R two things: what to call the new object (a data frame, really) that we're creating, and what numerical summary we would like. The code below summarizes median debt for the colleges in the dataset by calculating the average of median debt for all institutions.

Notice that inside the mean command

```
df%>%
   summarize(mean_debt=mean(grad_debt_mdn,na.rm=TRUE))

## # A tibble: 1 x 1

## mean_debt

## <dbl>
## 1 19646.
```

Quick Exercise Summarize the average entering SAT scores in this dataset.

Combining Commands

We can also combine commands, so that summaries are done on only a part of the dataset. Below, we summarize median debt for selective schools, and not very selective schools.

```
df%>%
  filter(stabbr=="CA")%>%
  summarize(mean_adm_rate=mean(adm_rate,na.rm=TRUE))

## # A tibble: 1 x 1
## mean_adm_rate
## <dbl>
## 1 0.592
```

Quick Exercise Calculate average earnings for schools where SAT>1200 & the admissions rate is between 10 and 20 percent.

Mutate

mutate is the verb for changing variables in R. Let's say we want to create a variable that's set to 1 if the college admits less than 10 percent of the students who apply.

```
df<-df%>%
  mutate(selective=ifelse(adm_rate<=.1,1,0))</pre>
```

Or what if we want to create another new variable that changes the admissions rate from its current proportion to a percent?

```
df<-df%>%
  mutate(adm_rate_pct=adm_rate*100)
```

To figure out if that worked we can use summarize

```
df%>%
  summarize(mean_adm_rate_pct=mean(adm_rate_pct,na.rm=TRUE))
```

```
## # A tibble: 1 x 1
## mean_adm_rate_pct
## <dbl>
```

1 67.9

Quick exercise: create a new variable that's set to 1 if the college has more than 10,000 undergraduate students

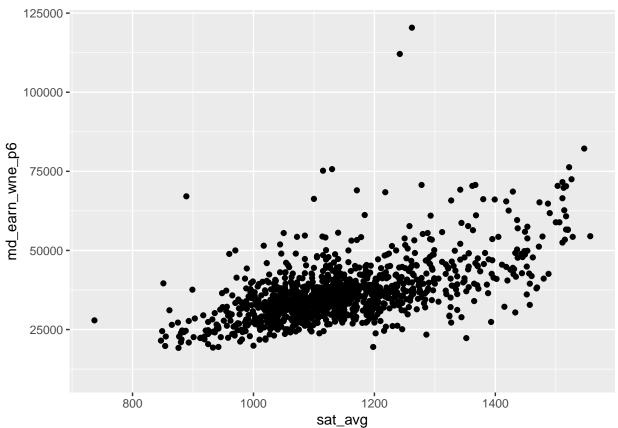

Plotting Data

Plotting data is another key skill as we're getting started. We're going to do a LOT more plotting, but let's just quickly look at the relationship between two variables using a plot. The basic tool for plotting in r is ggplot. To create a plot, we specify what goes on the x and y axis in an "aesthetics" argument, which is called aes. We then say what we want to draw on the plot—in this case a point for each case, which means we want to use geom_point.

Below is a plot of earnings of by SAT scores

```
## Plotting: bivariate
df%>%
    ggplot(aes(x=sat_avg,y=md_earn_wne_p6))+
    geom_point()
```

Warning: Removed 1348 rows containing missing values (geom_point).

Quick exercise: plot earnings by admission rate only for schools in California Quick exercise replicate the above plots, but put debt level on the y axis.
